More Design Tables and writing R models

Comparing experimental designs with Replicates and Subsamples

Standard Errors and Estimated Standard Errors

Fitting models in R

- 1) Write the model
- 2) Pass it to the function to fit the model: **lm()** or **lmer()**
- 3) Pass the result to a function to get estimates, SE, CI, etc
emmeans(), **contrast()**, etc

Writing the model

- 1) Response ~ every variable in Treatment + Design
with # levels < # responses
combined with “+”
- 2) Any variable that is a **EU** gets declared with (1|X)
+ Variable => + (1|Variable)
call these “random”
- 3) Replicate variables combined with treatments are random
+ (1|Replicate:Treatment)
This can be omitted for narrower scope
- 4) If any random variable is included, use lmer(). Otherwise use lm()

For our purposes, the only difference between these functions is the type of model statement they allow

The underlying code is very different

Some arguments of emmeans are different

| | | | | | | # people | # measures | #EU | |
|----|------|--------------|-----|--------------|-----|--------------|------------|-----|----|
| | | Sit | | Stand | | | | | |
| 1) | Jill | <div>X</div> | Bob | <div>X</div> | Amy | <div>X</div> | 80 | 80 | 80 |

| Structure | Variable | Type | #levels | Replicate | EU |
|-----------|----------|------|---------|-----------|--------|
| Treatment | Posture | Cat | 2 | None | Person |
| Design | Person | Cat | 80 | | |
| Response | Pulse | Num | 80 | | |

Write the model: **lm(Pulse ~ Posture)**

1) Response ~ every variable in Treatment + Design

with # levels < # responses
combined with “+”

2) Any variable that is a **EU** gets declared with (1|X)
+ Variable => + (1|Variable)
call these “random”

3) Replicate variables combined with treatments are random
+ (1|Replicate:Treatment)

This can be omitted for narrower scope

4) If any random variable is included, use lmer(). Otherwise use lm()

| | | Jill | | Bob | | Amy | # people | # measures | #EU |
|----|----|-------|----|-------|----|-------|----------|------------|-----|
| 2) | T1 | Sit | T1 | Stand | T1 | Sit | 40 | 80 | 80 |
| | T2 | Stand | T2 | Sit | T2 | Stand | | | |

| Structure | Variable | Type | #levels | Replicate | EU |

| | Trial | Cat | 2 | | |
| | Person: Trial | Cat | 80 | | |
| | Person: Posture | Cat | 80 | | |
| Response | Pulse | Num | 80 | | |

Write the model: **lm(Pulse ~ Posture + Person + Trial)**

1) Response ~ every variable in Treatment + Design

with # levels < # responses

combined with “+”

2) Any variable that is a **EU** gets declared with (1|X)

+ Variable => + (1|Variable)

call these “random”

3) Replicate variables combined with treatments are random

+ (1|Replicate:Treatment)

This can be omitted for narrower scope

4) If any random variable is included, use lmer(). Otherwise use lm()

| | | | | | | | | | |
|----|------|-----------------|--|-------|-----------------|-----|-----------------|------------|-----|
| | | Sit | | Stand | | Sit | # people | # measures | #EU |
| 3) | Jill | <div>X</div> T1 | | Bob | <div>X</div> T1 | Amy | <div>X</div> T1 | | |
| | | <div>X</div> T2 | | | <div>X</div> T2 | | 40 | 80 | 80 |

| Structure | Variable | Type | #levels | Replicate | EU |
|-----------|---------------|------|---------|-----------|--------|
| Treatment | Posture | Cat | 2 | None | Person |
| Design | Person | Cat | 40 | | |
| | Trial | Cat | 2 | | |
| | Person: Trial | Cat | 80 | | |
| Response | Pulse | Num | 80 | | |

Write the model: **lmer(Pulse ~ Posture + (1|Person) + Trial)**

1) Response ~ every variable in Treatment + Design

with # levels < # responses
combined with “+”

2) Any variable that is a **EU** gets declared with (1|X)
+ Variable => + (1|Variable)
call these “random”

3) Replicate variables combined with treatments are random
+ (1|Replicate:Treatment)

This can be omitted for narrower scope

4) If any random variable is included, use lmer(). Otherwise use lm()

Why don't we use Trial as a **Replicate** in 2) and 3)?

| | | | | | | | | | | |
|----|------|-------|----|-------|-------|-----|-------|----------|------------|-----|
| | | Jill | | Bob | | Amy | | # people | # measures | #EU |
| 2) | T1 | Sit | | T1 | Stand | T1 | Sit | 40 | 80 | 80 |
| | T2 | Stand | | T2 | Sit | T2 | Stand | | | |
| | | Sit | | Stand | | Sit | | # people | # measures | #EU |
| 3) | Jill | X | T1 | Bob | X | T1 | Amy | X | T1 | |
| | | X | T2 | | X | T2 | | X | T2 | |
| | | | | | | | | 40 | 80 | 80 |

In both cases, we have 2 trials, each with observations of sitting and standing

We could get a “direct” estimate of the standing effect in each trial

Benefit

Control for changes in Pulse / treatment effect between trials

Cost

With only 2 trials, we only have $(n-1) = 1$ degree of freedom

$t_c(\alpha = 0.05) = 12.7$ (huge confidence intervals)

Why?

Trials are replicates if our goal is to extrapolate to **new trials**

Otherwise, we are limited to the **average** of these two trials

Are we concerned about the treatment effect **changing** between our two trials?

Are all treatment effects **the same** if we do only 1 trial?

Efficiency of Experimental Designs

| | | Jill | Bob | Amy | # people | # measures | #EU |
|----|----|-------|-------|-------|----------|------------|-----|
| 2) | T1 | Sit | Stand | Sit | 40 | 80 | 80 |
| | T2 | Stand | Sit | Stand | | | |

$$\hat{\delta}_{B-A} = \frac{1}{n} \sum \hat{\delta}_j$$

Direct estimate = average of n observations

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

| | | Sit | Stand | Sit | # people | # measures | #EU |
|----|------|-----|-------|-----|----------|------------|-----|
| 1) | Jill | X | | | 80 | 80 | 80 |
| | Bob | | X | | | | |
| | Amy | | | X | | | |

$$\hat{\delta}_{B-A} = \hat{\mu}_B - \hat{\mu}_A$$

Indirect estimate of δ

$$\hat{\mu}_A = \frac{1}{n_A} \sum \hat{\mu}_{Aj} \quad \hat{\mu}_B = \frac{1}{n_B} \sum \hat{\mu}_{Bj}$$

direct estimates of μ_B and μ_A

$$\sigma_r(\hat{\mu}_i) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

$$\sigma_r(\hat{\delta}) = \sqrt{\sigma_r^2(\hat{\mu}_B) + \sigma_r^2(\hat{\mu}_A)}$$

Add the two variances

Because errors ϵ_B and ϵ_A are independent

Use different EU

Efficiency of Experimental Designs

| | | Sit | | Stand | | Sit | | | |
| 1) | Jill | X | | Bob | X | Amy | X | 80 | 80 |

$$\sigma_r(\hat{\delta}) = \sqrt{\sigma_r^2(\hat{\mu}_B) + \sigma_r^2(\hat{\mu}_A)}$$

Indirect Standard Error

$$\sigma_r(\hat{\mu}_i) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

Direct Standard Error

population = TRUE **Standing pulse**
$$\mu_{Aj}$$
sample size = # replicates/level

measurements = Estimates of Standing pulse
$$\hat{\mu}_{Aj} = y_{Aj}$$

$$\sigma_r(\hat{\mu}_A) = \sqrt{\frac{\sigma_{\mu_A}^2 + \sigma_r^2(\hat{\mu}_{Aj})}{40}}$$

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_{\mu_B}^2 + \sigma_r^2(\hat{\mu}_{Bj})}{40} + \frac{\sigma_{\mu_A}^2 + \sigma_r^2(\hat{\mu}_{Aj})}{40}}$$

Efficiency of Experimental Designs

Design 2

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_\delta^2 + \sigma_r^2(\hat{\delta}_j)}{40}}$$

40
↖
people

Design 1

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_{\mu_B}^2 + \sigma_r^2(\hat{\mu}_{Bj})}{40} + \frac{\sigma_{\mu_A}^2 + \sigma_r^2(\hat{\mu}_{Aj})}{40}}$$

40 40
↖ ↖
people # people
Standing Sitting

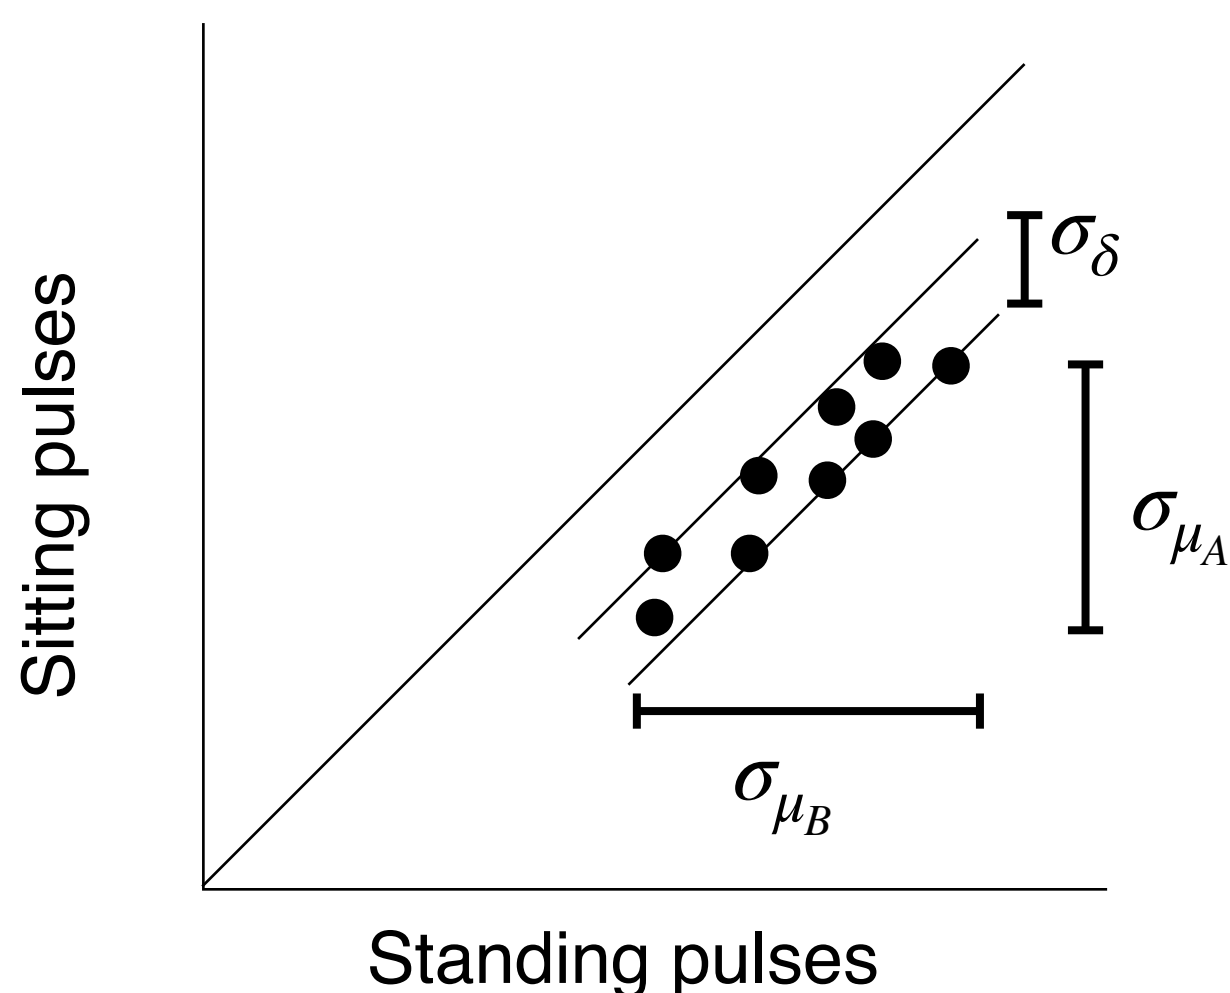

Which is bigger: measurement error for $\hat{\delta}_j$ or measurement error for $\hat{\mu}_{Bj}$ or $\hat{\mu}_{Aj}$?

$\sigma_r^2(\hat{\delta}_j)$ is 2x as big because it's from 2 separate pulse measurements (σ_m^2)

$$\sigma_r^2(\hat{\delta}_j) = 2\sigma_m^2, \sigma_r^2(\hat{\mu}_{ij}) = \sigma_m^2$$

Which is bigger: TRUE variance of **effects** or TRUE variance of **sitting(standing) pulses**?

$\sigma_{\mu_i}^2$ is generally bigger because μ_{Bj} and μ_{Aj} are **correlated**

$$\delta_j = \mu_{Bj} - \mu_{Aj}$$

When you add two **correlated** variables, the total variance is less than the sum of each variance

Efficiency of Experimental Designs

Design 2

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_{\delta}^2 + 2\sigma_m^2}{40}}$$

people

Design 1

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_{\mu_B}^2 + \sigma_m^2}{40} + \frac{\sigma_{\mu_A}^2 + \sigma_m^2}{40}}$$

people
Standing

people
Sitting

If the variances of Sitting and Standing are the same
 And the sample sizes are the same, we can simplify

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{2\sigma_{\mu_i}^2 + 2\sigma_m^2}{40}}$$

Since $\sigma_{\delta}^2 < 2\sigma_{\mu_i}^2$, Design 2 has a smaller standard error

With same # measurements and #EU, but fewer people

What about Design 3?

| | Sit | Stand | Sit | # people | # measures | #EU | | | | | | | | | | | | |
|----|---|-------|-----|----------|------------|---|---|----|---|----|---|---|----|---|----|--|--|--|
| 3) | Jill | Bob | Amy | 40 | 80 | 40 | | | | | | | | | | | | |
| | <table><tr><td>X</td><td>T1</td></tr><tr><td>X</td><td>T2</td></tr></table> | X | T1 | X | T2 | <table><tr><td>X</td><td>T1</td></tr><tr><td>X</td><td>T2</td></tr></table> | X | T1 | X | T2 | <table><tr><td>X</td><td>T1</td></tr><tr><td>X</td><td>T2</td></tr></table> | X | T1 | X | T2 | | | |
| X | T1 | | | | | | | | | | | | | | | | | |

| X | T2 | | | | | | | | | | | | | | | | | | | |

$$\sigma_r(\hat{\delta}) = \sqrt{\sigma_r^2(\hat{\mu}_B) + \sigma_r^2(\hat{\mu}_A)}$$

Indirect Standard Error

$$\sigma_r(\hat{\mu}_i) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

Direct Standard Error

population = TRUE **Standing pulse** μ_{Aj}

population variance = $\sigma_{\mu_i}^2$ (same as Design 1)

measurements = Estimates of Standing pulse $\hat{\mu}_{Aj} = \frac{y_{Aj_1} + y_{Aj_2}}{2}$

measurement variance is 1/2 that of Design 1: $\frac{\sigma_m^2}{2}$

samples / treatment level is 1/2 that of design 1

Final Standard Error:

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{2\sigma_{\mu_i}^2 + 2/2\sigma_m^2}{20}}$$

Efficiency of Experimental Designs

Design 2

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\sigma_{\delta}^2 + 2\sigma_m^2}{40}}$$

Design 1

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{2\sigma_{\mu_i}^2 + 2\sigma_m^2}{40}}$$

Design 3

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{2\sigma_{\mu_i}^2 + 2/2\sigma_m^2}{20}}$$

Smaller population variance

Smaller measurement error

Smaller sample size (#EU / level)

| | Sit | | Stand | | Sit | | | | | | | | | |
|------|---|---|-------|----------|-----|---|---|---|----------|-----|---|---|---|----------|
| Jill | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> | X | X | T1 T2 | Bob | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> | X | X | T1 T2 | Amy | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> | X | X | T1 T2 |
| X | | | | | | | | | | | | | | |
| X | | | | | | | | | | | | | | |
| X | | | | | | | | | | | | | | |
| X | | | | | | | | | | | | | | |
| X | | | | | | | | | | | | | | |
| X | | | | | | | | | | | | | | |

Repeated measures of the same sample are **subsamples**

Not declaring EU causes **pseudoreplication**

More subsamples = less measurement error / EU

More subsamples = fewer EU

Optimal number of subsamples

Tradeoff between EU and subsamples based on cost

Optimal number of subsamples $\sqrt{\frac{k}{c}}$

$c = \frac{\text{cost}/(\text{subsample} + \text{measurement})}{\text{cost}/(\text{EU})}$

$k = \frac{\sigma_m^2}{\sigma_{\mu_i}^2} \left(\frac{\frac{\hat{\mu}_{ij1} - \hat{\mu}_{ij2}}{2}}{\frac{\mu_{i1} - \mu_{i2}}{2}} \right)^2$

half the difference among replicate measures of the same individual

half the difference among different individuals

| k | c | Optimal number of subsamples | |
|----|------|------------------------------|-----|
| .5 | 1 | .7 | → 1 |
| 1 | 1 | 1 | → 1 |
| 2 | 1 | 1.4 | → 1 |
| 4 | 1 | 2 | → 2 |
| .5 | 1/10 | 2.2 | → 2 |
| 1 | 1/10 | 3.1 | → 3 |
| 2 | 1/10 | 4.5 | → 4 |

Estimated Standard Errors for each design

Design 2 “Direct”

$$\hat{\delta}_{B-A} = \frac{1}{n} \sum \hat{\delta}_j$$

Direct estimate = average of n observations

TRUE
Standard
Error:

$$\sigma_r(\hat{\delta}) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

Estimated
Standard
Error:

Sample Variance of $\hat{\delta}_i \approx$ Variance of TRUE values + Variance of error

$$s_{\hat{\delta}}^2 = \frac{\sum (\hat{\delta}_j - \hat{\delta})^2}{n - 1}$$

$$\text{SED} = \sqrt{\frac{s_{\hat{\delta}}^2}{n}}$$

This is an estimate of $\sigma_r(\hat{\delta})$

Degrees of
Freedom

(n-1) from denominator of $s_{\hat{\delta}}^2$

Estimated Standard Errors for each design

Design 1 “Indirect”

$$\hat{\delta}_{B-A} = \hat{\mu}_B - \hat{\mu}_A \quad \text{Indirect estimate of } \delta$$

$$\hat{\mu}_A = \frac{1}{n_A} \sum \hat{\mu}_{Aj} \quad \text{direct estimates of } \mu_B \text{ and } \mu_A$$

TRUE
Standard
Error:

$$\sigma_r(\hat{\mu}_i) = \sqrt{\frac{\text{Variance of population} + \text{Variance of measurements}}{\text{Sample size}}}$$

Estimated
Standard
Error:

Sample Variance of $\hat{\mu}_{ij} \approx$ Variance of TRUE values + Variance of error

$$s_{\hat{\mu}_i}^2 = \frac{\sum (\hat{\mu}_{ij} - \hat{\mu}_i)^2}{n_i - 1} \quad \text{Observed variance of estimates around their mean}$$

$$\text{SEM} = \sqrt{\frac{s_{\hat{\mu}_i}^2}{n_i}}$$

TRUE
Standard
Error:

$$\sigma_r(\hat{\delta}) = \sqrt{\sigma_r^2(\hat{\mu}_B) + \sigma_r^2(\hat{\mu}_A)}$$

Estimated
Standard
Error:

$$\text{SED} = \sqrt{\frac{s_{\hat{\mu}_B}^2}{n_B} + \frac{s_{\hat{\mu}_A}^2}{n_A}}$$

Problem:

Degrees of
Freedom

$(n_B - 1)$ from $s_{\hat{\mu}_B}^2$ or $(n_A - 1)$ from $s_{\hat{\mu}_A}^2$?

Can't use 2 degrees of freedom for the t-distribution

Best Df is closer to the **smaller** of $(n_B - 1)$ and $(n_A - 1)$

Solution: **Pooled** $s_{\hat{\mu}}^2$

Sample Variance of $\hat{\mu}_{ij} \approx$ Variance of TRUE values + Variance of errors

if Variances of pulses are similar for both treatments

And measurement errors are similar

We can **pool** all deviations together into a **pooled** $s_{\hat{\mu}}^2$

$$s_{\hat{\mu}}^2 = \frac{\sum (\hat{\mu}_{Bj} - \hat{\mu}_B)^2 + \sum (\hat{\mu}_{Aj} - \hat{\mu}_A)^2}{(n_B - 1) + (n_A - 1)}$$

All deviations² from the sample means

independent deviations per treatment

Estimated
Standard
Error:

$$\mathbf{SED} = \sqrt{\frac{s_{\hat{\mu}}^2}{n_B} + \frac{s_{\hat{\mu}}^2}{n_A}}$$

If variances are equal, this is a **better** (more accurate) estimate of $\sigma_r(\hat{\delta})$

Here, we have a single df to use for confidence intervals:

Degrees of
Freedom

$$(n_B - 1) + (n_A - 1)$$

Key points:

Follow the sample sizes for **each treatment level**

Each is used 2x

We will always use the **pooled** $s_{\hat{\mu}}^2$ in this class because of limitations of the `lm()` and `lmer()` functions

Estimated Standard Errors for each design

| | Sit | Stand | Sit | # people | # measures | #EU | | | | | | |
|----|---|-------|-----|---|------------|-----|---|---|---|----|----|----|
| 3) | Jill | Bob | Amy | | | | | | | | | |
| | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> ^{T1} _{T2} | X | X | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> ^{T1} _{T2} | X | X | <table><tr><td>X</td></tr><tr><td>X</td></tr></table> ^{T1} _{T2} | X | X | 40 | 80 | 40 |
| X | | | | | | | | | | | | |
| X | | | | | | | | | | | | |
| X | | | | | | | | | | | | |
| X | | | | | | | | | | | | |
| X | | | | | | | | | | | | |
| X | | | | | | | | | | | | |

Which equation for s^2 and SED?

Which components will **tend to be** different from Design 1 / 2 ?

* our data will be different, so all estimates will be different *

$$\hat{\delta}_{B-A} = \hat{\mu}_B - \hat{\mu}_A \quad s_{\hat{\mu}}^2 = \frac{\sum (\hat{\mu}_{Bj} - \hat{\mu}_B)^2 + \sum (\hat{\mu}_{Aj} - \hat{\mu}_A)^2}{(n_B - 1) + (n_A - 1)}$$

$$\text{SED} = \sqrt{\frac{s_{\hat{\mu}}^2}{n_B} + \frac{s_{\hat{\mu}}^2}{n_A}}$$

$s_{\hat{\mu}}^2$ will **tend to be** smaller because of less measurement error

n_B and n_A will be smaller (or equal) because of costs

If so, SED *might be* larger and DF would be smaller

Rules for making Design Table

Include all variable necessary to describe the experiment

Treatments: Variables we want to study

Response: One Variable, always numeric

Design

EU of the Treatment variable(s)

any Replicate and Replicate:Treatment

Variable with a unique level for each observation (Response)

Any other variable to describe the experiment

Check variable relationships: nested, aliased and crossed

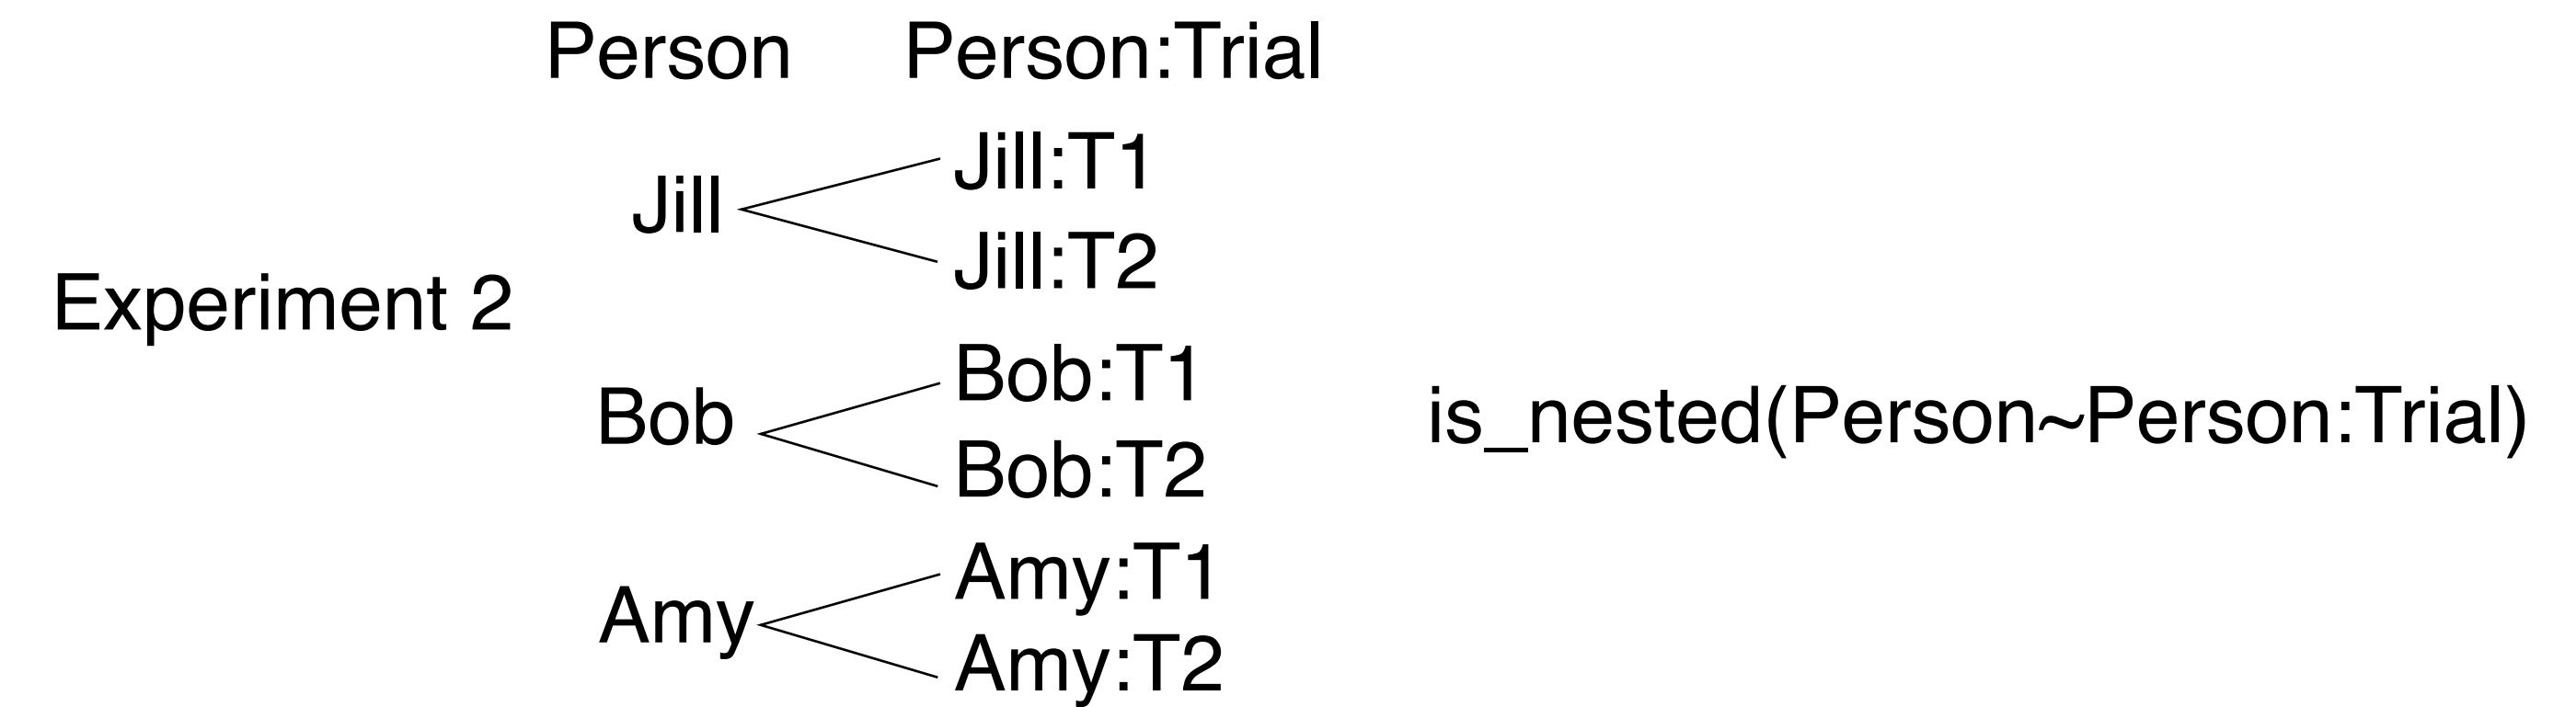

EU Variable must be **nested** in the Treatment variable

If two variables are **aliased**, keep only 1 of them

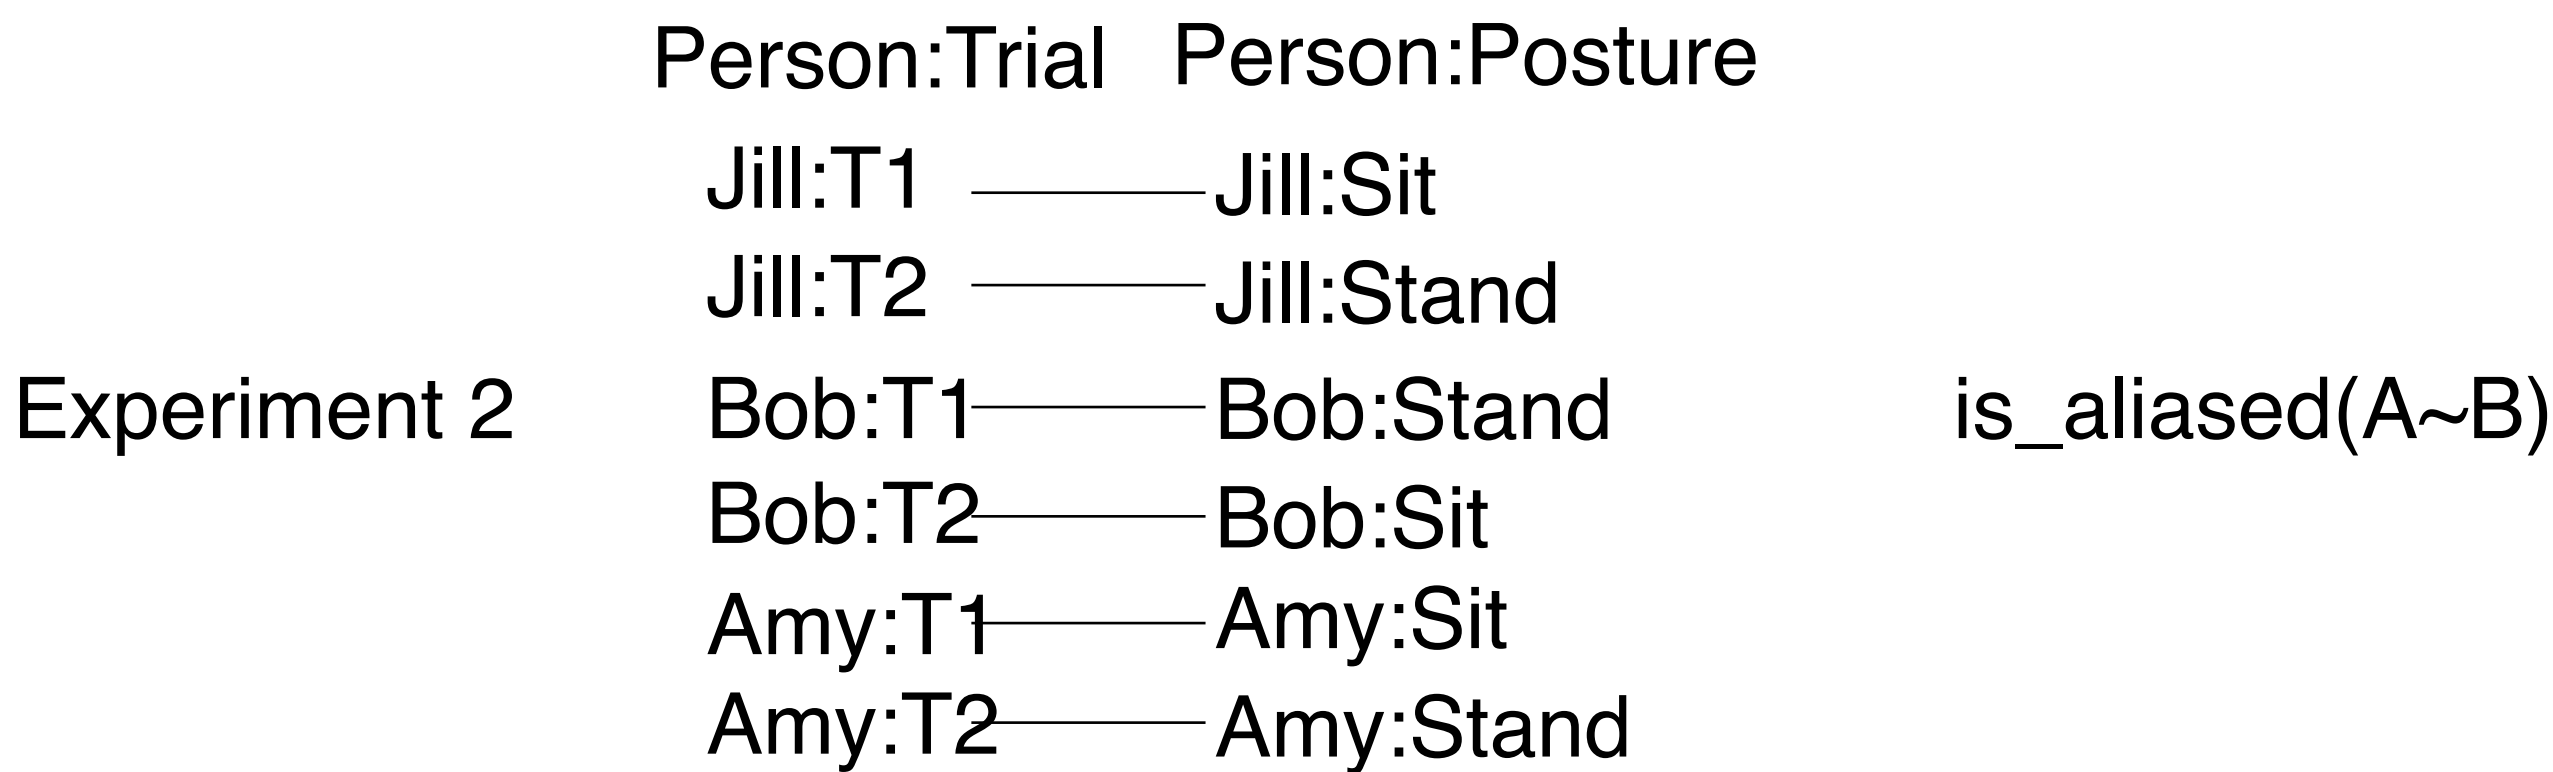

If two variables are **crossed**, keep only both

Relationships among variables

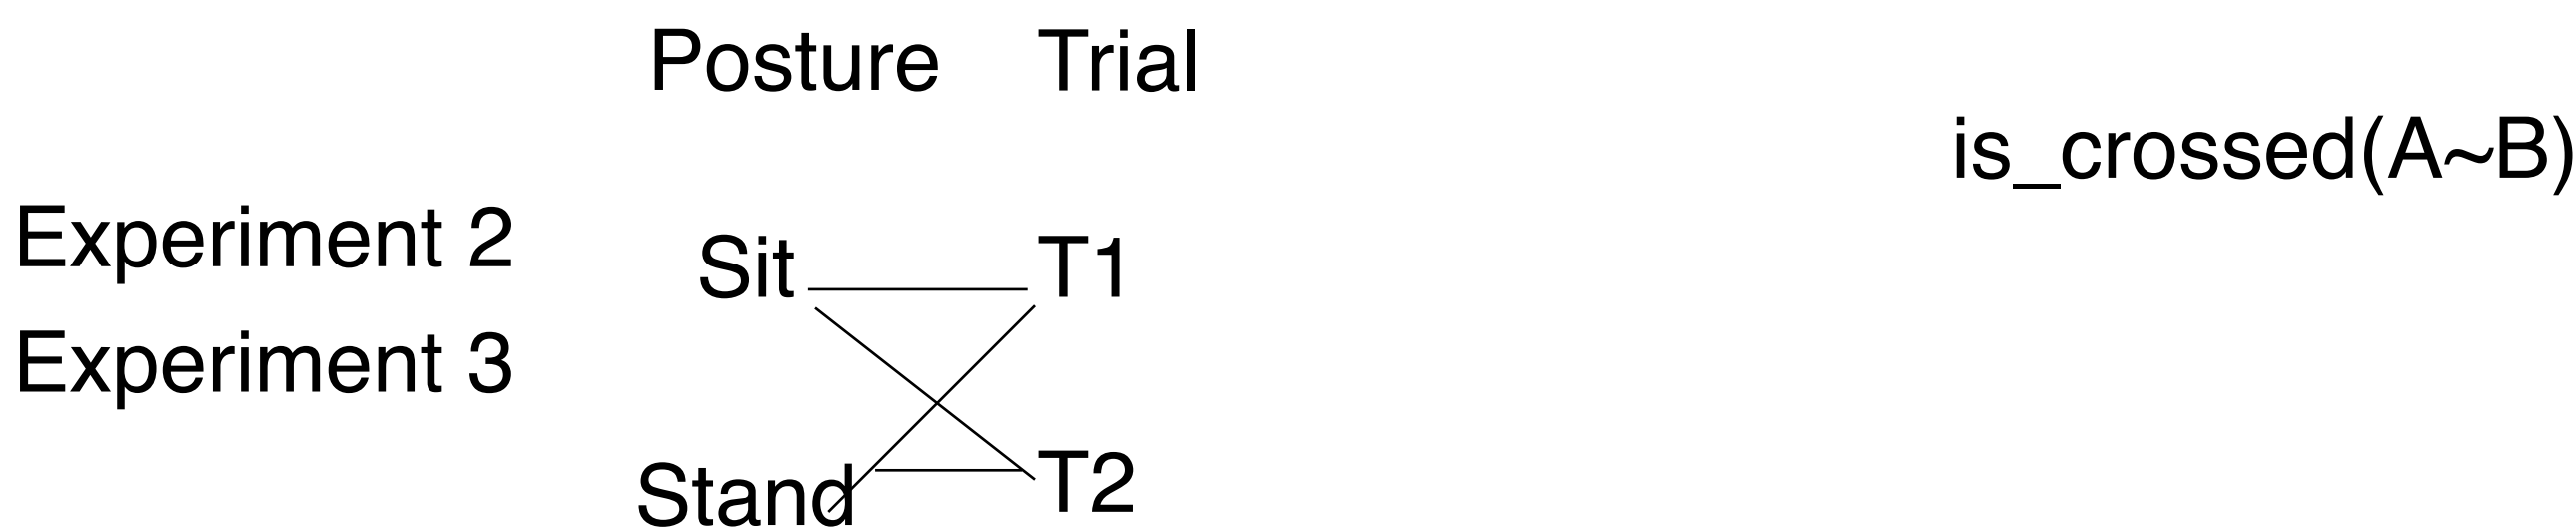

nested many:one Keep both, if 1 first is random, so is second

aliased one:one Keep one, particularly EU

crossed many:many Keep both

Rules for making Design Table

Include all variable necessary to describe the experiment

Treatments: Variables we want to study

Response: One Variable, always numeric

Design

EU of the Treatment variable(s)

any Replicate and Replicate:Treatment

Variable with a unique level for each observation (Response)

Any other variable to describe the experiment

Check variable relationships: nested, aliased and crossed

EU Variable must be **nested** in the Treatment variable

Label as EU:Treatment

If two variables are **aliased**, keep only 1 of them

If one is an EU, keep that one!

If two variables are **crossed**, keep both

Treatments are crossed with their Replication variable
